

Solubility

Rules

- Salts containing Group I elements (Li^+ , Na^+ , K^+ , Cs^+ , Rb^+) are soluble.
- Ammonium ion is soluble (NH_4^+)
- Nitrate ion is generally soluble (NO_3^+)
- (Cl^- , Br^- , I^-) are generally soluble. EXCEPTIONS - (Ag^+ , Pb^{2+} , and Hg_2^{2+})
- Most silver salts are insoluble. EXCEPTIONS - (AgNO_3 , and $\text{Ag}(\text{C}_2\text{H}_3\text{O}_2)$)
- Most sulfate salts are soluble (SO_4^{2-}) EXCEPTIONS - (BaSO_4 , PbSO_4 , and SrSO_4)

Polyatomic Ions

NO_3^- Nitrate	NO_2^- Nitrite
SO_4^{2-} Sulfate	SO_3^{2-} Sulfite
PO_4^{3-} Phosphate	PO_3^{3-} Phosphite
CO_3^{2-} Carbonate	HCO_3^- Hydrogen Carbonate
CN^- Cyanide	NH_4^+ Ammonium
OH^- Hydroxide	ClO^- Hypochlorite
CH_3CO_2^- Acetate	

Nomenclature

Ionic

- Name the cation
- Then name the anion
- Add -ide to the end of the anion
- Balance it when you have various charges on metals
- EX: CaCl_2 - Calcium Chloride
- EX: $\text{Fe}(\text{OH})_2$ - Iron (II) Hydroxide. Because OH is 1- and you have 2. For an overall 2-. Iron has to be a positive charge of 2+ so that its balanced.

Covalent/Molecular

- Use prefixes EXCEPTION: No “mono” on the first atom if there is only one of them
- Add -ide to the end of the second atom
- EX: CO_2 - Carbon Dioxide
- EX: SF_6 - Sulfur Hexafluoride

Number	Prefix
1	Mono
2	Di
3	Tri
4	Tetra
5	Penta
6	Hexa
7	Hepta
8	Octa
9	Nona
10	Deca

Molarity

Molarity = (Moles of solute)/(Liters of solution)

Concentration = Determine concentration by multiplying the given M by how many there are in the equation. EX:

Map

Ba(OH)₂ is a strong electrolyte.
Determine the concentration of each of the individual ions in a 0.250 M Ba(OH)₂ solution.

[Ba²⁺] = M

[OH⁻] = M

Explanation Previous View Solution Check Answer Next Exit

Ba(OH)₂ dissociates in aqueous solution according to

$$\text{Ba}(\text{OH})_2(s) \xrightarrow{\text{H}_2\text{O}} \text{Ba}^{2+}(aq) + 2\text{OH}^-(aq)$$

Therefore, the solution is 1(0.250 M) = 0.250 M in the cation, and 2(0.250 M) = 0.500 M in the anion.

Temperature

Celsius to Fahrenheit	$^{\circ}\text{F} = 9/5 (^{\circ}\text{C}) + 32$
Kelvin to Fahrenheit	$^{\circ}\text{F} = 9/5 (\text{K} - 273) + 32$
Fahrenheit to Celsius	$^{\circ}\text{C} = 5/9 (^{\circ}\text{F} - 32)$
Celsius to Kelvin	$\text{K} = ^{\circ}\text{C} + 273$
Kelvin to Celsius	$^{\circ}\text{C} = \text{K} - 273$
Fahrenheit to Kelvin	$\text{K} = 5/9 (^{\circ}\text{F} - 32) + 273$

Map 

For the following chemical reaction

$$2\text{HBr}(aq) + \text{Ba}(\text{OH})_2(aq) \longrightarrow 2\text{H}_2\text{O}(l) + \text{BaBr}_2(aq)$$

 Write the net ionic equation, including the phases.

$$\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$$

▼ Explanation

[Previous](#)
[View Solution](#)
[Check Answer](#)
[Next](#)
[Exit](#)

Start by writing the ionic equation.

$$2\text{H}^+(aq) + 2\text{Br}^-(aq) + \text{Ba}^{2+}(aq) + 2\text{OH}^-(aq) \longrightarrow 2\text{H}_2\text{O}(l) + \text{Ba}^{2+}(aq) + 2\text{Br}^-(aq)$$

HBr is split up into ions because it is a strong acid. Ba(OH)₂ and BaBr₂ are split up into ions because they are aqueous, soluble ionic compounds. Water is left in molecular form because it is not an ionic compound nor a strong acid.

Now, notice that 2Br⁻ cancels from each side. Ba²⁺ also cancels leaving

$$2\text{H}^+(aq) + 2\text{OH}^-(aq) \longrightarrow 2\text{H}_2\text{O}(l)$$

Then divide ^ it all by 2 because its equivalent to $\text{H}^+(aq) + \text{OH}^-(aq) \rightarrow \text{H}_2\text{O}(l)$
